Tittel:

High Availability System Based on Separated Control and  
Traffic System

FULLMEKTIG:

Oslo Patentkontor AS, Postboks 7007M, 0306 Oslo

### Field of the Invention

The invention relates to High Reliability systems for Real  
5 Time Traffic.

### Background of the invention

1. Separasjon kontroll og trafikk.

a. SW I kontroll funksjon.

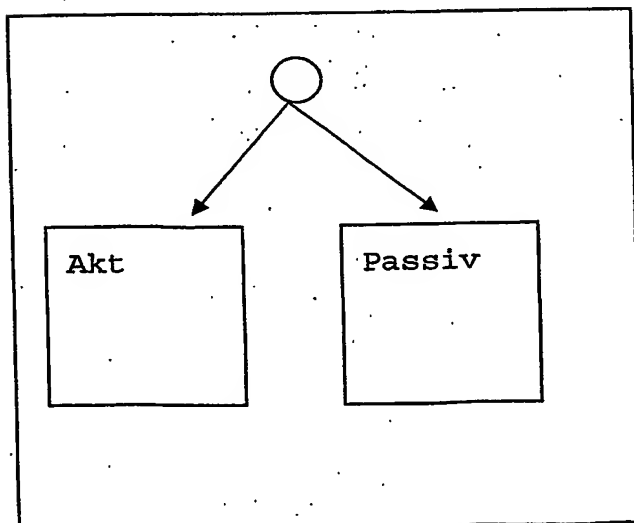

b. SW upgrade.

10 c. Avbruddsfri SW upgrade.

d. Selvttest uavhengig av trafikken

e. Telecom Datasvitsjer.

Ny software inn i passiv bank.

Summary Of the invention

Digital bilde 1.

- 5 Oppgradering: I prinsippet; peke på Passiv og gjøre passiv aktiv og aktiv passiv. Før dette kjøres et testrun på passiv, for blant annet å se at det ikke foreligger fatale feil ved oppgraderingssoftwaren, som for eksempel kan føre til at en mister kontakt med programmet. Ved test OK settes
- 10 passiv bank lik aktiv bank. En kan selvfølgelig skifte dette tilbake når som helst.

En algoritme gjelder for aksept/ikke aksept av software:

Spørsmål: Akseptere software?

- Ja; -Svitsje over manuelt, det vil si skifte aktiv og
- 15 passiv bank manuelt.

Ja; - svitsje over automatisk etter testrun.

Ved ja på spørsmålene foretas en svitsj. ==> laster kun ned nødvendige filer.

---

Konfigurasjonsfilhåndtering se bilde 2 digitalt kamera

- 20 Et poeng ved det distinkte skillet mellom traffic og control er at en da kan kjøre trafikk uavhengig av hva som skjer med control biten, dette er vesentlig for tilgjengelighet, upgrade, temperaturkontroll, service etc.

## 2. Temperatur kontroll.

- a. Effekt kan reduseres ved at control funksjonen kan settes ut av drift, som følge av separasjonen vil dette ikke føre til endringer i trafikksituasjonen.

Normalt vil temperturkontrollen gi en hardware shutdown for å beskytte kortet mot skader, således vil en ikke få forvarsler, en vil også få tap av tilgjengelighet uten at en mottar forvarsler. Prinsippet som anvendes i oppfinnelsen er et to trinnsprinsipp, en kunne tenkt seg flere trinn, men det har ingen hensikt....

- 10 Om HTT = 1 then control = ut av drift  
 Om HTT = 1 then send alarm til drift management systemet  
 Om ETT = 1 then hardware shutdown, for å beskytte hardware  
 mot brannskader. Alarm sendes drift management systemet.

Syklus beskrivelse for figuren:

- 15 0 --> 1 normal drift  
 1 --> 2 kontroll funksjonene settes ut av drift  
 automatisk, trafikken påvirkes ikke, grunnet separasjon,  
 alarm sendes OAM.  
 2 --> 3 Automatisk hardware shutdown, det vil si at  
 20 trafikk og kontroll settes ut av drift, alarm til drift og  
 management systemet. Systemet "sover"  
 3 --> 4 Systemet starter automatisk opp igjen, men uten  
 kontroll funksjoner status gjøres kjent for kontroll og  
 management systemet.  
 25 4 --> Systemet går automatisk tilbake til normal drift.

Hensikten:

10 Om HTT = 1 then control = ut av drift  
 Om HTT = 1 then send alarm til drift management systemet  
 Om ETT = 1 then hardware shutdown, for å beskytte hardware  
 mot brannskader. Alarm sendes drift management systemet.

Syklus beskrivelse for figuren:

15 0 --> 1 normal drift  
 1 --> 2 kontroll funksjonene settes ut av drift  
 automatisk, trafikken påvirkes ikke, grunnet separasjon,  
 alarm sendes OAM.  
 2 --> 3 Automatisk hardware shutdown, det vil si at  
 20 traffikk og kontroll settes ut av drift, alarm til drift og  
 management systemet. Systemet "sover"  
 3 --> 4 Systemet starter automatisk opp igjen, men uten  
 kontroll funksjoner status gjøres kjent for kontroll og  
 management systemet.  
 25 4 --> Systemet går automatisk tilbake til normal drift.

Hensikten:

-kan arbeide ved høyere omgivelsestemperatur --> økt kapasitet, redusert vifteavhengighet.

- gir økt tilgjengelighet, idet trafikken ikke påvirkes av at kontroll funksjonaliteten koples ut.

- 5 -genmerelt positivt med bedre temeperaturstyring, for holdbarhet, service etc....

Det anvendes redundante viftesystemer, slik at eneste single point of failure finnes for vifte styringskortet!!  
Mer om det senere....

10

### 3. Tilgjengelighet/BPI bus

General availability node/ protected interfaces, line protection interface.

Tilgjengelighet.

15

MTBF: mean time between failure

MITR: mean time to repair

$Tilgjengelighet = MITR / MTBF$

20

Dersom NPU faller ut: (NPU Node Processing Unit)  
ingenting skjer med trafikken dersom ikke dette skjer ved MITR.1

Uten separasjon så vil kontrollsysteet påvirke tilgjengelighet.

Med 155 Mbit/s inteface (selv medtatt komponent aldring)  
--> 7000 år tilgjengelighet (service medtatt)

25

### 4. Skalerbarhet:

Referer digitale bilder

ASIC distribuert svitsjoing av porter. DFistribuerte systemer skalerer godt nedover, men vanligvis ikke oppover.

- 5 Skalerer godt, med få kort fordi sentrale komponenter ikke medtas, det vil si at nodeprisen for små node blir lav, kun ta med NPU.

A

10 It is an object of the present invention to provide a method avoiding the above described problems.

The features defined in the independent claims enclosed characterize this method.

In particular, the present invention provides

## 15 Introduction

Based on these principles the Traffic Node's architecture and functionality are described. The description is a principle/concept description which means that some things might be differently implemented in specific releases of  
20 the product.

The document provides an entry point into the TN system documentation and refers to the appropriate documents.

## Readers Guide

Figure 1 Readers Guide documents for Traffic Node

## The Traffic Node and its environment

### The microwave network

The TN is targeted to work in the PDH/SDH microwave transport network for the LRAN 2G and 3G mobile networks, as shown in Figure .

Figure 2 Application of the TN in the Lower Radio Access Network  
End-to-end connectivity in the TRAFFIC NODE microwave network is based on E1 network connections, i.e. 2Mbit/s. These E1 network connections are transported over TRAFFIC NODE microwave links. The capacity of these microwave links can be the following:

- 2 E1, i.e. 2x2Mbit/s
- 1xE2, i.e. 1x8Mbit/s
- 2xE2, i.e. 2x8Mbit/s
- 1xE3+1xE1, i.e. 34Mbit/s+2Mbit/s
- 1xSTM-1, i.e. 155Mbit/s

Connectivity to/from the microwave network is provided through:

- G.703 E1 interface
- STM-1 interface

This is illustrated on Figure 3.

The microwave network consists of the following network elements:

- TRAFFIC NODE E providing:
  - Medium Capacity Radio, 2x2-34+2Mbit/s
  - PDH access on E1, E2 and E3 levels
- TRAFFIC NODE High Capacity providing:
  - High Capacity Radio, 155Mbit/s
  - Optical/electrical STM-1 access
- Traffic Node comprising:
  - E1 cross-connect
  - Generic network interfaces:
    - PDH access on E1 level
    - SDH access through optical/electrical STM-1
- TRAFFIC NODE E compatible Medium Capacity Radio
- TRAFFIC NODE E co-siting solution

Figure 3 LRAN network and the role of various TRAFFIC NODE sub-networks.

Figure 4 shows that Traffic node can be managed by:

- 5       • A Local Craft Tool (EEM), this is computer with a web browser that connects with the Embedded Element Manager(EEM).
- Remotely by TRAFFIC NODE Manager, using a combination of both EEM and SNMP interface.
- 10       • Remotely by a operator specific Operations Support System (OSS) or Network Management System (NMS).

Figure 4 O&M environment of Traffic Node

The DCN-IP network

- 15       In order to perform management of the TNs a Data Communications Network (DCN) is required. This is an IPv4 based DCN that uses in-band capacity on the transport links by means of unnumbered PPP links. This requires a minimum of IP network planning and doesn't require
- 20       configuration of the TN in order to connect to the DCN. OSPF is used as a routing protocol. Together an Ethernet-based site-LAN connection to the TN, the TN DCN can be connected to any existing IP infrastructure as shown in figure 5. TN communicates with the following services:
- 25       • DHCP, for assignment of IP addresses to equipment on the site-LAN, e.g. the EEM. The TN provides DHCP relay functionality for this.
- NTP; the TN uses NTP for accurate time keeping
- FTP, used for software upgrade and configuration up
- 30       and download.
- The Network Element Manager (NEM) uses SNMP for monitoring and configuring the TN.
- The EEM is a PC that communicates HTML pages containing JavaScript over HTTP with the Embedded
- 35       Element Manager (EEM) in the TN by means of a web browser.

Figure 5 The TN IP based DCN

## TN Principles

This chapter describes the architecture of the TN, which consists of a Basic Node (BN) and Applications, and the principles on which it is based. Before looking at the architecture it self, the principles that for the basis for the architecture design are described below.

### Detailed description of the invention

#### A first preferred embodiment of the invention

#### A second preferred embodiment of the invention

10

### Modularity

The TN is based on a modular principle where HW and SW application can be added to the system through the use of uniform mechanisms.

- 15 This allows for a flexible upgrade from both a HW and SW perspective, hence, new functionality can be added with minimal effort (at least from the end customer's point of with).

- 20 The TN Basic Node, TN BN, provides re-usable HW and SW components and services for use by application designers.

- 25 Software of the TN BN and various applications, like MCR and STM-1, are integrated by the well defined interfaces. These interfaces are software function calls, file structures, hardware busses or common hardware and software building blocks. The well defined interfaces enable the application flexibility in design. As long as they conform to the interfaces there is a high level of freedom in how both software and hardware are implemented.

Figure 6 TN modularity

### Scalability

The principle of modularity and distribution of the system through the busses and their building blocks makes the system linearly scalable.

The distributed switching hardware architecture allows for the size of the node to scale from large node (20 APUs) down to small nodes (1 or 2 APUs).

The alternative centralised switching architecture allows for scaling up to higher capacity where the distributed architecture doesn't allow for capacity increase.

Offering both a distributed switching architecture as well as being prepared for a centralised switching architecture enables scalability of traffic rates required today and in the future.

Functional scalability is achieved through a distributed software architecture which allows for new functionality (applications) to be added through well defined interfaces.

#### Separated Control and Traffic systems

A principle used to improve robustness is to separate the control and traffic system of the TN. The control system configures and monitors the traffic system. Whilst the traffic system routes the traffic through the TN. Failure and restarts of the control system will not influence the traffic system.

Separation of control and traffic system applies throughout the node and its PIUs.

This enables e.g. software upgrade of the TN without disturbing traffic. In the architecture description later it will be pointed out whether a component is part of the control or the traffic system.

#### Redundancy

A principle that provides robustness to the TN is 'no single point of failure' in the traffic system. This means that traffic is not disturbed as long as one failure occurs in the system. This is realised by redundant traffic busses, optional redundant power and traffic protection mechanisms. More details on the redundancy of the various system components can be found in the following architecture sections.

The architecture allows for application to implement redundancy, like MSP 1+1 for the STM1- application or 1+1 protection for the MCR link.

### In service upgrade

The principle of in-service upgrade, i.e. upgrade without disturbance of traffic, of both software and hardware functionality in the Traffic Node is applicable for:

- Upgrade of all software in the Traffic Node to a new System Release
- Hot-insertion of PIUs, that are automatically upgraded to software matching the existing System Release of the Traffic Node.
- Hot-swap of PIUs where a new PIU inherits the configuration of the old PIU.
- 

### APU handled by one Application

Every APU in the traffic node handled by one application. One application can however handle several APUs, even of a different type.

### Future packet support

For every new feature designed in the Traffic Node future support for packet data, like ATM and IP, is taken into account.

### Use of industry standards

The extensive use of de-facto industry standards enables the use of third party products, competence acquisition, risk reduction and greater functionality differentiation.

### Functional distribution Basic Node versus Applications

Some basic principles have been established in traffic node when it comes to functional distribution between a common Basic Node and Applications. In this model applications are concerned with providing physical bearers for end-to-end connections, i.e. physical and server layer links for PDH traffic. This entails:

- Line interfaces
- Server layer multiplexing (everything 'below' PDH)
- Fault propagation (on link level)
- Physical line protection
- Physical line diagnostics like loops and BERT
- Peripheral equipment handling, e.g. RAU.

Whereas Basic Node provides:

- Generic/standard network interfaces
- PDH Networking
- PDH multiplexing
- 5 • Fault Propagation (network level)
- Cross-connection
- Network protection, i.e. SNCP
- Network layer diagnostics like loops and BERT
- DCN handling, i.e. IP and it's services like routing,  
10 FTP etc.
- Equipment Handling on node and PIU levels
- Maintaining consistent configuration of the node, e.g.  
a System Release.
- Means to an application to communicate with /control  
15 its APUs.

#### TN Architecture

Figure 7 shows a complete overview of the TN architecture. In a TN there will be one component called TN BN and several different instances of the TN Application component. Both kind components can consist of both  
20 hardware and software.

The next sections will first look at the overall software and hardware architecture of the TN. Afterwards the basic node architecture and application architecture will be  
25 described more detailed.

Figure 7 TN architecture

#### TN Software Architecture

The TN software consists of three major software component types:  
30

- Basic Node Software (BNS)
- Application Node processor Software (ANS)
- Application Device Processor Software (ADS).

35 As shown in Figure 7, TN BNS and the various applications communicate through the Basic Node Functions (BNF) interface. This interface consists of two protocols:

- AgentX that together with its SNMP master and SNMP sub-agents acts as a object request broker used to  
40 realise an extensible SNMP agent. The SNMP sub-agents subscribe with the SNMP-master in the BNS to receive

the SNMP requests that the applications wants to handle. The SNMP master in its turn acts as a post-master that routes SNMP requests to the SNMP sub-agents in the applications.

- CLI based on the same principles as AgentX but then for the CLI protocol. This interface is used for CLI requests, collection of configuration data for persistent storage and configuration at start-up.
- Basic Node Functions(BNF) signals, a proprietary message interface for inter-process communication.

Both protocol peers on the application side are contained in the Application Interface Module(AIM) as shown in figure 8.

Figure 8 TN software architecture

#### TN Hardware Architecture

The Traffic Node's hardware architecture consists of Basic Node Hardware (BNH) in which Application Plug-in-Units (APU) can be placed. The BNH provides various communication busses and a power distribution bus between the various PIUs in the TN. The busses themselves are part of the backplane, i.e. TN BN, whilst PIUs interface to these busses through TN BNH Building Block (BB) is shown in figure 9.

Figure 9 TN BNH busses and building blocks

As an illustrative example figure 10 shows the busses and their location on the AMM 20p backplane.

Figure 10 The TN AMM 20p Backplane

In the next sections these busses and their corresponding building blocks will be discussed.

#### SPI Bus

SPI is a low speed synchronous serial interface used for equipment handling and control of:

- APU cold and warm resets
- status LEDs and BRS

- Inventory data, like product number, serial number, asset identifier etc.
  - Temperature supervision
  - Power supervision
  - 5   • BPI disable/enable
  - PCI fault handling
  - General purpose ports
- The SPI BB is implemented in a Complex Programmable Logic Device (CPLD). The SPI bus and BBs are part of TN's control system.

## 10   PCI Bus

The PCI bus is a multiplexed address/data bus for high bandwidth applications and is the main control and management bus in the TN-Node. Its main use is communication between NP Software (NPS) and Application DP Software (ADS), TDM BB and ASH like Line Interface Units (LIU). The PCI bus is part of the control system. The PCI BB is implemented in a Field Programmable Gate Array (FPGA).

## TDM Bus

20   The TDM bus implements the cross-connects functionality in the TN. Its BB is implemented in an Application Specific Integrated Circuit (ASIC). Characteristics are:

- 32 port per ASIC, where each port can have a capacity of 8kBit/s to 45MBit/s
- 25   • The bus with TDM BBs provide a non-blocking switching capacity of ~400 E1 ports (800Mbit/s), i.e. 200 bi-directional cross-connects.
- Redundant switching function
- Cross connection
- 30   • Routing DCN to the IP router on the NPU.
- Support for PDH synchronization hierarchy.

TDM bus and its BBs are part of the traffic system.

## Power

35   Power distribution, optional redundant (have to install two PFUs) as being part of the traffic system. DC/DC conversion is distributed and present at every PIU.

## Synchronisation busses

40   The PDH synchronisation bus provides propagation of synchronisation clock between PIUs as well distributes the local clock.

The SDH synchronisation bus provides propagation of synchronisation clock between PIUs.

Being part of the traffic system, both PDH and SDH synchronisation busses are redundant.

#### 5 BPI busses

BPI-2 and BPI-4 can be used for application specific inter-APU communication. The communicating APUs must then be located in the same group of 2 respectively 4 slots, i.e. located in specific neighbouring slots in the TN rack. The

10 BPI busses are controlled by the application.

#### Point-to-Point bus

The Point-to-Point (PtP) bus is meant for future central switching of high-capacity traffic.

#### Programming bus

15 The programming bus is intended as JTAG bus for programming the FPGAs in the node.

#### Basic Node Architecture

The TN BN consists in the TN product structure of two components:

- 20 • TN BNS, TN Basic Node Software
- TN BNH, TN Basic Node Hardware

Although the TN EEM is not a part of the TN BN in the product structure, in practice it is a necessary part when building TN Applications that need to be managed by the

25 EEM. That is why in the rest of this document the TN EEM is regarded as a part of TN BN.

These three TN BN components will interface to their peer components in the TN Application through well defined interfaces.

#### 30 TN Basic Node Software

The TN BNS realises control and management of the TN BN and its TN BNH BB that reside on the various APUs. Therefore it is part of TN's control system, and delivers its services to the TN Applications. It is part of the TN

35 control system and not of the traffic system.

The main Basic Node architectural concept is its distributed nature. For the SNMP and CLI interfaces there is a Master/Sub-Agent architecture, where the master acts as a postmaster and routes requests to the sub-agents as shown in figure 8. Each sub-agent handles its part of the SNMP object tree or its sub-set of the CLI commands.

Figure 11 TN BNS

#### TN BNS External Interfaces

10 The TN BNS provides the following external interfaces:

- HTML/HTTPS, the embedded manager, TN EEM, sends HTML pages to a browser on the operator's computer. HTTPS is used to provide encryption especially on the username and password of the HT pages.
- 15 • DCN Services, various IP protocols such as:
  - DNS
  - NTP for synchronisation of the real-time clock
  - FTP for software upgrade and configuration up/download
  - Telnet for CLI configuration
  - 20 • DHCP for TN acting as an DHCP relay agent
- CLI, over Telnet, limited configuration of the TN through Cisco alike commands.
- SNMP, O&M interface using SNMPv3 to configure the node, gets its status and send traps to the manager.
- 25 Configuration by means of SNMPv1/v2 is optional.

#### TN Embedded Element Manager

The TN can be managed through either the SNMP interface or a WEB based embedded manager. This embedded manager consists of two parts:

- 30 • A WEB-server located in the TN BNS able to execute PHP script
- HT pages with embedded PHP script, denoted as TN EEM. These pages can be divided into three categories:
  - Framework, generic pieces of HTML/PHP code part of the TN BN
  - 35 • Basic Node management, part of TN BN
  - Application management, AWEB, part of the TN application

Figure 12 TN EEM: Framework and Basic Node

The WEB server receives an URL from the EEM and retrieves the page. Before sending the page to the EEM it interprets the PHP code, which is replaced with the return values of the PHP call. The WEB-server interfaces to the SNMP-master in the TN BNS by executing the PHP SNMP function calls. The TN EEM is part of the TN control system.

As described above interfaces the TN EEM to the WEB-server in the TN BNS through HTML with embedded PHP script.

#### TN Basic Node Hardware

Figure 13 TN BNH

The TN BNH consists of:

- TN BN backplane providing the previously described busses
- Building blocks that enable APUs to interface these busses:
  - SPI
  - PCI
  - Power
  - TDM
  - TN BN PIUs:
    - NPU, Node Processor unit running TN BNS and ANS. The NPU also provides:
      - 8 E1 Traffic Interfaces
      - V.24 interface
      - Ethernet interface
      - 3 digital input and outputs
    - PFU, Power Filter Unit providing power to the other PIUs.

- FAU, although not a real PIU in the sense that it is not couple directly to the busses in the backplane.

- TN BN Mechanics:

- Rack, providing space to 20 or 6 large format PIUs (i.e. excluding PFUs and FAU)

Interface towards TN BNS

The BNS-BNH interface is register and interrupt based.

### Application Architecture

Figure 14 shows the internal components of an TN Application that will be discussed in the following sections:

- TN EEM: AWEB, application specific HTML/PHP pages for management of the application

- ANS, Application Node Software is the software needed for the application running on the NPU, i.e. on Linux OS.

- ADS Application Device Software, is the software running on the processor on the APU, in case a processor is present.

- APU, Application Plug-in Unit, is the application board.

Figure 14 TN Application architecture

TN Application software (ANS+ADS)

### Figure 15 TN Application Software

The application software consists of:

- ANS running on the NP (see also figure 15) on the NPU. This software is running even if the corresponding APUs are not present in the TN. It is the control software for the application and as for all software on the NPU, failure will not cause traffic disturbance.

- ADS is located on the APU if the APU houses one or more processors.

Figure 16 shows the internal ANS architecture, where the AIM, Application Interface Management module, houses SNMP and CLI sub-agents that are responsible for the application specific SNMP objects/CLI commands.

- 5 The ADD, Application Device Driver, contains application specific device drivers and real-time ANS functions.

The architecture of the ADS is very application specific and interface only to the ANS and not to any part of the TN BNS directly.

10

#### Figure 16 TN ANS architecture

##### Interface towards BNS

The BNF, Basic Node Function, provides the interface between ANS and BNS. It comprises of 3 sub-interfaces:

- 15 • CLI, protocol for the AIM for CLI sub-agent to CLI-master communications. Used for e.g. persistent configuration storage.
- AgentX, protocol for the AIM for SNMP sub-agent to SNMP master communications. Used for SNMP configuration and  
20 alarms etc.
- BNF Signals for message based communication between AIM and BNS. This can in principle also be used between other processes.

##### TN Application EEM

- 25 The application specific WEB pages are located on the NPU. These pages contain HTML and PHP script that is executed by the WEB-server in the TN BNS. The WEB-server executes the PHP SNMP function calls and talks to the SNMP master, which its turn delegates the request to the SNMP sub-agent  
30 residing in the AIM of the respective ANS.

#### Figure 17 TN Application EEM

##### Interface towards TN EEM

- 35 The AWEB interfaces to the rest of the TN EEM through a naming convention for the respective HTML/PHP files.

## TN Application hardware

The hardware of the application is called an APU, Application Plug-in Unit. The application specific hardware uses the TN BNH BBs, to interface to the TN BNH and so to the other PIUs in the TN as shown in figure 18.

Figure 18 TN Application Hardware

Figure 19 shows how an APU is build-up from Application Specific Hardware (ASH) and the TN BNH BBs.

Figure 19 TN APU

Mechanically the APU interfaces with the TN BNH rack and backplane.

## TN Functionality

In this section the TN functionality as described in the various Functional Specifications is mapped onto the architecture described previously.

### Equipment Handling

Equipment comprises of:

- Installation and repair
- Restart
- Supervision
- Inventory and status
- Node Configuration Handling

Inventory and status

The SPI bus is used to scan the TN for PIUs, Hardware inventory data of these PIUs is retrieved from the SPI BB by the TN BNS EHM, through a SPI device driver. This data is represented in both the ENTITY-MIB as well as the TN-MODULE-MIB handled by the EHM.

Inventory data on the software on the various APUs is handled by the corresponding ANS that holds its part of inventory table in the TN-SOFTWARE-MIB.

Equipment status on the TN and PIUs is partly controlled through the SPI BB for faults like high temperature, restart and board type. Other possible faults on equipment are communicated from ANS to EHM in the BNS. These faults will often be communicated over PCI from an ADS to its ANS.

### Equipment Installation and Repair

Installation of a new TN is regarded as part of equipment handling, but is actually a set of sub-functionalities like DCN configuration, software upgrade password setting (SNMP Module) and configuration download under direction of the Equipment Module.

Hot-swap is supported to enable plug & play on all PIUs except NPU. It uses both SPI and PCI busses and is the responsibility of the Equipment Module in the BNS. Plug & play for PIUs that have to be repaired is realised by saving the PIUs configuration for  $\tau_6$  minutes period after it has been removed. A new PIU of the same type can then inherit this configuration when inserted within  $\tau_6$  minutes after removal.

### Restarts

The node and APUs can be cold and warm restarted as a consequence of external management requests or software/hardware errors. Warm restarts will only affect the control system whilst a cold restart also affects the traffic system. Cold and warm restarts of APU is communicated using the SPI.

### Node configuration persistence

Running configuration is stored persistent in the TN's start-up configuration file in flash memory. The CLI master in the TN BNS invites all TN BNS modules and the AIMS in the ANS to submit their running configuration to the start-up configuration file.

Saving the running configuration will also lead to saving the new start-up configuration file to an FTP server using the FTP client in the TN BNS.

### Supervision

The following sub-systems are supervised for software/hardware errors:

- NPU Processes by a watchdog reporting errors in an error log available to management.
- ANS supervision;

- the Equipment Module will poll the AIM to check whether is alive, using a BNF call
- the AIM monitors it's ANS internal processes
- the ANS is responsible for supervision of the ADS processes and DP-NP communication links (SPI & PCI)
- 5   • PCI bus
- SPI bus
- APU supervision of power and temperature is supervised by the BNS using the SPI.
- 10   • FAN Supervision through SPI by the BNS.

Detection of errors will in most cases lead to a restart or reset of the failing entity as a identification and repair mechanism.

### Traffic Handling

- 15   Traffic handling functionality deals with traffic handling services offered by the TN BN to the TN Applications. The following sections describe sub-functions of traffic handling.

#### Cross connect

- 20   Cross-connections between interfaces, offered by applications to the TN BN, are realised in TN BNH by the TDM bus and the TDM BBs, under software control by the traffic handler in the TN BNS. Applications register their TDM ports indicating the speed. After this TN BN can
- 25   provide cross-connections with independent timing of the registered ports.

- 30   Bit pipes offered by applications on TDM ports are chopped in 64Kbps timeslots which are send on the TDM bus and received by another TDM BB on the bus and compiled into the original bit-pipe. Figure 20 shows and example of a cross-connection.

Figure 20 Example of a bi-directional 3\*64Kbs cross-connection between the two APUs

## Sub-Network Connection Protection

SNCP provides 1+1 protection of connections in the network, offered by the TN Applications on TDM ports, over sub-networks. Outgoing traffic is transmitted in two different directions, i.e. TDM ports, and received from one of these directions. Faults detected on the receiving line cause the TN BNS to switch to the TDM port from the other direction.

As with cross-connections, SNCP is implemented in TN BNH by the TDM bus and TDM BBs. TN BNS traffic handler controls management of the SNCPs.

Main characteristics of the SNCP:

- permanently bridged
- unidirectional switched
- non-revertive
- requires no extra capacity on the TDM bus
- part of control system.

## Equipment protection

Equipment protection is provided by TN BN in the form of the TDM bus, the TDM BBs and BNS. It provides protection between two APUs based on equipment failures. An application can order this service between two APUs from BNS. BNS will then set-up the TDM BBs on both APUs and switch from one TDM BB to the other upon an equipment failure.

## Performance Management

BNS, and more precisely the ASIC DD, collects performance report on TDM ports every  $\tau_1$  second, from either the TN Application, the ADD in the ANS, or from the TDM BB. This data is reported further to the Performance management in the traffic module of TN BNS. Here the TN BNS offers the service to update current and history performance records of the TDM port based on the  $\tau_1$  reports. These performance records are available to the ANS to be presented to management in an application specific SNMP MIB.

To have synchronised PM intervals applications will collect their application specific PM data based on the same  $\tau_1$  signal as the BNS.

The TN BNS, or more specifically the traffic module, also keeps track of performance threshold crossings in case of TDM BBs.

All communication between the BNS and ANS uses BNF messages.

## Figure 21 PM handling in TN

### 5 Connection Testing

For testing purposes the TN BNS provides a BERT service to applications. Where a PRBS can be sent on one port per ASIC per APU concurrently and a BER measurement is performed in the receiving direction.

- 10 For protected connections, i.e. SNCPS, one BERT s provided per node.

The TN BNS also realises connections loops on the TDM bus by programming the TDM BB to receive the same time-slot as transmitted.

- 15 On the physical transmission layers line and local (or inward) loops can be used in the fault location process.

### Alarm Handling

- Defects in the TN, that need to be communicated over the SNMP interface to a manager, are detected by the  
20 corresponding resource handler. The resource handler, e.g. an ANS or BNS process, will be first informed about the defect through SPI or an ADD that reports over PCI. The defect will be reflected in the SNMP status objects hold by the ANS.

- 25 Alarm suppression is performed in the TN in order to prevent alarm storms and simplify fault location. For this purpose defects for various sources are correlated. An application can do this for its own defects but can also forward a defect indication to the BNS in order to suppress  
30 BNS alarms. A general rule is that equipment alarms suppress signal failure alarms who in their turn suppress performance alarms. Also lower layer (closer to the physical layer) alarms will suppress higher layer alarms.

- 35 Using the AgentX interface the AIM will report an alarm for the defect to the Alarm handler functionality in the SNMP module in the BNS. Alarms will be stored in a current alarm list and a notification log. It is then up to the manager to subscribe on these notifications that are sent a SNMP traps in IRP format.

Figure 22 TN Alarm Handling overview

Software Upgrade

5 The software upgrade functionality allows the operator to download a new System Release, that consists of a NPU Load module and several DP load modules, on a node per node basis. Topology and available DCN bandwidth may allow for several nodes to be upgraded concurrently. However, which upgrade strategy is used is up to the NMS.

10 The TN BNS upgrades its self plus all ANS. The ANS are responsible for upgrading the corresponding DPs using the TN BNS's FTP client and RAM disk as temporary storage medium before transporting the load module to all the APUs over PCI to be stored into the APU passive flash memory. This happens while the software in the active flash memory  
15 is executed.

20 The software upgrade process is fail-safe in that respect that after a software upgrade the operator has to commit the new software after a test run. If a commit is not received by the node, it will fall back to the old software. It is also possible to have the node self execute a rudimentary test without the need for the operator to commit.

Phase	Inform	Upgrade	Restart	Test/Commit	Active
Description	TN retrieve information on the system Release and load modules to upgrade to.	TN downloads (FTP) all load modules that require an upgrade in to RAM disk at NPU and burns them into the NPU/APU passive flash memory.	TN warm restart to test new software	Manager/Node commits new software. Failure leads to software fall-back	After commit new system release is active. Only a fall-back on NPU software can be performed.

## TN: Availabillity models and calculations

### 5 Abstract

This document describes the availability models that serve as the basis for the design of the TN. It also includes the calculated failure rates and MTBR figures for the TN.

### Prerequisites

- 10 The reliability calculation for the TN connections are based on the following prerequisites:

### Calculation method

- 15 All calculations are based on MIL-HDBK-217F Notice 1 with correction factors. The correction factor is based on actual experience data and compensates for the difference in use of a commercial and a military system. A military system is normally used for a short interval with long periods of storage whereas a commercial system is in constant use.

### 20 E1 connection

The connections are bi-directional connections on one interface type.

Figure 23 E1 carried on one interface.

- 25 For terminals the picture below applies.

Figure 24 E1 carried on a terminal

### Redundancy Model

The calculations are based on the general model. With fault detection in the control parts, with  $\lambda_R = \lambda_S$ ,  $\mu_R = \mu_U = \mu_C$  ( $\mu = 1/\text{MTTR}$ ). Generally  $\mu_U$  can be expected to be shorter as a service affecting failure will be raised as a major or critical alarm.

$$U = (2\lambda_T + \lambda_C + 6\lambda_T\lambda_C/\mu)\lambda_T/\mu^2, \text{ and as } \lambda = U*\mu, \lambda = (2\lambda_T + \lambda_C + 6\lambda_T\lambda_C/\mu)\lambda_T/\mu$$

Figure 25 Redundancy model - basis for calculations

### MTTR

MTTR = 24h, ( $\mu = \mu_U = \mu_C = 1/\text{MTTR} = 1/24$ ) This is a simplification as the traps indicating faults are divided into the categories: warning, minor, major and critical. The simplified meanings of these severities are: information, control function failure, loss of redundancy and loss of traffic. It is reasonable to expect a short MTTR to a critical alarm whereas a warning or minor may have a longer MTTR. Still 24h is used as a common repair time.

### Temperature

The calculations are related to a 40 °C ambient component temperature. The TN-E estimates are all done at 40 °C and the correction factor may include temperature compensation if the actual temperature is different from this. Therefore the TN estimates are set at the same temperature. The correction of the temperature at some units is related to the specific cases where the units are consuming little power and thus have a relative temperature difference with respect to the other units.

### PIU function blocks

All PIUs are divided into three parts. Control, traffic and parts common to both. This gives the following simple model for the traffic and control function availability:

5

Figure 26 PIU function blocks

10

The control part is any component whose failure does not affect the traffic. The traffic part is components whose failure only affects the traffic. The common part is components that may affect both the traffic and the control. Some examples:

- Traffic: ASIC, BPI, Ella, interfaces, muxes
  - Control: PCI, DP, SPI EEPROM
  - Common, Power, SPI CPLD, SPI temp sensor
- 15 The control block and the traffic block are repaired individually through separate restarts.

## The General TN availability models

### Basic node availability models

#### Cross connect

5 The cross-connect function in the TN is distributed and is implemented through the ASIC circuits.

10 The failure rate of an E1 connection through the ASIC is not the same as the MTBF of the circuit. The ASIC is divided into a port dependant part and the redundant cross-connect. The failure rate of one port (including scheduler) is 20% of the ASIC MTBF and the TDM bus (cross-connect) is 30% of the ASIC MTBF.

#### Figure 27 ASIC block structure

15 The model for the redundant cross-connect can be seen below:

#### Figure 28 TDM bus redundancy

From the following can be seen:

$$U_{\text{cross connect}} = (2\lambda_{\text{TDM}} + \lambda_{\text{PCI+NPU-C}} + 6\lambda_{\text{TDM}}\lambda_{\text{PCI+NPU-C}}/\mu)\lambda_{\text{TDM}}/\mu^2$$

20 As can be seen the TDM bus redundancy improves the failure rate by a factor of more than 50000. This makes the TDM bus interface insignificant and it is therefore omitted from the calculations. The ASIC contribution to the E1 failure rate is then 20% of the ASIC MTBF. This contribution is the  
25 port reference in the general availability model.

#### AMM 20p

The AMM 20p can be equipped with or without redundant PFUs. The two models for this are shown below:

Figure 29 AMM 20p with redundant power distribution

Figure 30 AMM 20p without redundant power distribution

The fan (FAU1) consists of one fan control board (FCB) and 3 fans. If one of the 3 fans fail a notification will be sent and the two remaining fans will maintain cooling in the repair interval. The FCB powers all 3 fans and is therefore a common dependency.

The power distribution in the AMM20p is redundant but the node may be equipped without redundant PFUS if so desired. The power distribution has a very high reliability even without the redundancy. This option is therefore generally viewed as a protection against failure of the external power supply rather than the node power distribution.

There is no dependency to a control function for the switchover between the redundant parts for the power or the fans.

The unavailability in a 2 of 3 system is given by the equation:

$U_{2/3} = U_1^2(3 - 2U_1)$  where  $U_1$  is the unavailability of one branch.

The Power distribution when redundant is a 1 of 2 system. The unavailability of this is given by the equation:  $U_{1/2} = U_1^2$

AMM6p

The model for the AMM 6p is shown below:

Figure 31 AMM 6p BN

The fan (FAU2) consists of one PCB with 2 fans. If one of the 2 fans fail a notification will be sent and the remaining fan shall maintain cooling in the repair interval. There is no dependency to a control function for the switchover between the redundant parts for the fans.

The fan is thus a 1 of 2 system. The unavailability of this is given by the equation:  $U_{1/2} = U_1^2$

General availability model - protected interfaces

Figure 32 General model for protected interfaces

This model is the basis for the design of protected interfaces in the TN node.

The level of redundancy in the basic node depends on the type of basic node. The cross-connect is redundant. This is  
5 always in operation and may not be turned off.

The line and equipment protection schemes vary from application to application. Generally the line protection is much quicker and is intended to maintain connectivity during line faults. The requirement is therefore that the  
10 traffical disruption as a consequence of line faults shall be less than  $\tau_4$  msec. The equipment protection is allowed to be slower ( $\tau_5$  sec.) as the MTBF of the protected parts are much better. Note that the line protection will repair many equipment faults as well.

#### 15 Simplified model - protected interfaces

The figure below shows a simplified model, which is used for the calulations.

Figure 33 Simplified model for protected interfaces

20 This model is used as the basis for the actual calculations as the separation of the blocks in the general model may be difficult. As an example of this consider a board that has the SDH multiplexers and the SOH termination in the same circuit. The line protection and the equipment protection  
25 availability are difficult to calculate as the circuits combine the functions. This is the case even though the implementation clearly separated.

This model will not provide as good results as the more correct general model since the simplification views the  
30 protection mechanisms as two equipment protected PIUs without the line protection

The redundant cross-connect is omitted from the calculations. The APU port is 20% of the ASIC -see chapter 0. The traffic functions of an APU is then used with 20% of  
35 the ASIC as the basis for the calculations.

From the following can bee seen:

$$U_{1+1} = \lambda_{BN-T} / \mu + (2\lambda_{APU-T:1+1} + \lambda_{(APU+NPU)-C} + 6\lambda_{APU-T:1+1}\lambda_{(APU+NPU)-C/\mu}) \lambda_{APU-T:1+1} / \mu^2$$

### General availability model - unprotected interfaces

The figure below shows the model for unprotected interfaces:

#### 5 Figure 34 General model - unprotected interfaces

This model is the series connection of the Basic Node and the traffic part of an APU.

Note that for unprotected interfaces the Basic Node is assumed to have non-redundant power.

#### 10 MCR availability

##### Prerequisites

- The MMU2 MTBF calculation is divided not only with respect to control and traffic but also with respect to the use of the PIU. When the unit is used in a 1+1 configuration the ASIC and Ella are not in use. Faults will then not be discovered in these components and the components are therefore not included in the calculation.
- The SMU2 MTBF calculation is divided not only with respect to control and traffic but also with respect to the use of the PIU. When the SMU2 is used as a protection unit, then the line interfaces are not in use. Faults will then not be discovered in these components and the components are therefore not included in the calculation.
- The calculations can be seen in chapter Feil! Fant ikke referansekilden..

Results and discussion

- 5 The calculated results can be seen in the table below.

	AMM20p	AMM6p	Requirement
MTBF for interfaces:	MTBF (y/f)	MTBF (y/f)	MTBF (y/f)
Unprotected radio interface	71	74	-
Protected radio interface *	256	232	-
Unprotected STM-1 interface	186	206	-
Protected STM-1 interface *	7121	1811	-
Unprotected E1 interface.	227	258	-
SNCP protected E1 interface *	7128	1812	-

MTBF for terminals:	MTBF (y/f)	MTBF (y/f)	MTBF (y/f)
Unprotected radio terminal	58	59	59

Protected radio terminal *	138	131	250
Unprotected STM-1 terminal	115	122	100
Protected STM-1 terminal *	288	258	250
Unprotected E1 terminal	129	139	100
SNCP protected E1 terminal *	288	258	250

Mean Time Between Repairs for:	MTBR (y/r)	MTBR (y/r)	MTBR (y/r)
Unprotected radio terminal	35	40	59
Protected radio terminal *	19	21	27
Unprotected STM-1 terminal	40	48	100
Protected STM-1 terminal *	26	31	50
Unprotected E1 terminal	53	67	100
SNCP protected E1	37	50	50

terminal *			
------------	--	--	--

Availabillity for terminals:			
Unprotected radio terminal	9,999524E-01	9,999538E-01	-
Protected radio terminal *	9,999802E-01	9,999790E-01	-
Unprotected STM-1 terminal	9,999762E-01	9,999776E-01	-
Protected STM-1 terminal *	9,999905E-01	9,999894E-01	-
Unprotected E1 terminal	9,999788E-01	9,999802E-01	-
SNCP protected E1 terminal *	9,999905E-01	9,999894E-01	-

Table 1: Summary of failure rates (\*AMM20p with protected PFU1)

5 The radio-terminal availability may be improved by changing  
 the way the E1s on the LTU 16x2 are handled. In TN a  
 failure of one interface will result in the restarting of a  
 complete board. This means that from availability point of  
 view the system punishes boards with many interfaces per  
 unit. If the fault handling procedure is changed so that a  
 10 fault on one interface only results in a restart of that  
 interface then the LTU 16x2 will improve its failure rate  
 by a factor of 3. This will give the following results for  
 the terminals:

MTBF for terminals:	MTBF (y/f)	MTBF (y/f)	MTBF (y/f)
Unprotected radio terminal	66	68	59
Protected radio terminal *	199	184	250
Unprotected STM-1 terminal	154	168	100
Protected STM-1 terminal *	800	602	250
Unprotected E1 terminal	303	361	100
SNCP protected E1 terminal *	800	602	250

Table 2: Improvement by changing the E1 fault handling

The calculations are based on the use of the LTU 16x2 for the terminal. For some cases it may be possible to use the local drop on the NPU 8x2 instead. If this is done then the results are as shown below:

MTBF for terminals:	MTBF (y/f)	MTBF (y/f)	MTBF (y/f)
Unprotected radio terminal	63	65	59
Protected radio terminal *	171	160	250
Unprotected STM-1	137	148	100

terminal			
Protected STM-1 terminal *	484	403	250
Unprotected E1 terminal	203	227	100
SNCP protected E1 terminal *	484	403	250

Table 3: NPU 8x2 used as terminal interface.

Notation

The symbol notation failure rates for PIUs is:  $\lambda_{\langle \text{unit/function} \rangle}$ -

5  $\langle \text{T/C} \rangle : \langle \text{operational mode} \rangle$  Where:

- unit/function is the PIU/function name e.g. MMU2, MCR or MCRTer
- T/C = Traffic/control.
- operational mode is usage, e.g. 1+1 or 1+0.

## TN: EQUIPMENT HANDLING

### Abstract

This document describes hardware and software equipment  
5 handling in the TN. Examples of this functionality are:

- Equipment start/restart
- Equipment supervision and redundancy
- Equipment installation, upgrade and repair
- Inventory management

10

The scope of the document is to specify the equipment  
handling functionality of the TN on system level. The  
15 functionality will be further detailed in Functional  
Descriptions (FD), Interworking descriptions (IWD) and  
design rules (DR).

### IMPROVEMENTS

The following is a list of possible improvements for the  
20 future:

- The APUs should possibly have the yellow LED on if the  
PCI bus is unconfigured. This would indicate to the service  
personnel that for reset, restarting or absent NPUs the  
APUs may be removed.
- 25 • Chapter describing management view including entity  
MIB.  
Principles regarding PIU, FAU, RAU should be included.
- PtP BPI handling has to be described.

## PRINCIPLES

The TN equipment handling is based on a few important principles:

### 5 Redundant traffical system

The traffical system is required to be configurable as redundant. It shall withstand one failure. It is assumed that the failure will be corrected before a second failure occurs. The fault identification is therefore required to  
10 be extensive. If a fault cannot be discovered it cannot be corrected.

This requirement makes it necessary to have redundant ATM switch and IP router slots in the subrack.

### Separated control and management system

15 The system is required to have the control system separated from the traffical system. The reason for this is that:

- The control system can be non-redundant. A failure in the control system will not influence the network connectivity. This greatly reduces cost and complexity.
- 20 • It simplifies in service upgrade. The control system can be taken out of service to be upgraded without any traffical impact.
- It enables extensive self-tests. The control system may be reset and any kind of self-test (within the control  
25 system) may be performed. This allows for self-test that have a high likelihood of providing a correct fault localisation to be executed.

### In service upgrade

30 The system shall be in service upgradeable. This means that without disturbing the established traffic it shall be possible to:

- Perform SW upgrade.
- Add new PIUs (requires hot swap for all but NPU).
- Remove/replace any replaceable unit (requires hot  
35 swap). If an APU is protected then the operation shall give

less than  $\tau_4$  msec. disturbance on the connections on that board. The operation shall not give any disturbance on any other connections.

#### NPU redundancy

- 5 The TN has a requirement to be prepared for NPU redundancy. This is to allow for:

• Higher control system availability. A failure in the control system may disconnect the DCN network. A redundant NPU may improve the control system availability and thus  
10 also the DCN availability.

• Easier maintenance. The redundant NPU solution may give a local configuration file backup. This simplifies the NPU repair procedures.

#### PFU redundancy

- 15 The power supply is a prerequisite for operation of the node. Redundant power inlet and distribution is vital in order to withstand one failure.

The two power systems shall both be active sharing the load. A failure in the power system shall not result in any  
20 disturbance of traffic or control and management systems.

• Double power inlet enables power redundancy in the site installation.

• Redundant PFU remove all possible single point of failure in the unit.

- 25 • Redundant PFU enables replacement of a PFU without any disturbance.

THE SPI BUS

The equipment handling in TN uses the SPI bus in the node as a central component therefore some of the main SPI functionality is described here.

5 The SPI bus is a low speed (approx. 1 Mbit) serial synchronous bus that is mandatory on all TN boards. The bus is controlled by the NPU. It is a single master bus over which the NPU may execute a set of functions towards the PIUs. These functions are:

- 10 • Place the board in cold and warm reset.
- Read an onboard EEPROM containing information about the board.
- Set alarm thresholds for the excessive and high temperature alarms.
- 15 • Control the LEDs (yellow and red) on the PIU front.
- Enable/disable: 2BPI, 4BPI, PtP-BPI interfaces, programming bus(PCI), and interrupts.

Over the SPI interface the NPU will be notified of the following:

- 20 • Temperature threshold crossing.
- PIU Power failure.
- PFU Input power failure.
- BR activation
- Board insertion/power-up
- 25 • PCI FPGA loading completion/failure
- PCI bus transaction failure.
- PCI capability (does the board have it or not)
- Fan failure.
- Application dependant interrupts (fan failure..)

The BNS will at start-up pass on to the applications the information found on the APUs SPI block. I.e.: the BNS will receive the temperature thresholds and will need to check them for validity, if incorrect change them to default values. The BNS will need to handle the NPU and PFU in a similar manner.

The SPI interrupts will result in a trap to the ANS. The ANS may in addition read and write to the SPI functions. This may serve as a means for a very low speed communication between the ANS and the APU (use of APORT).

The ANS can give the APU access to the SPI EEPROM by enabling bypass. This functionality is intended to be used for the redundant NPU solution. It may cause problems for the BN if this function is used by an application as the NPU loses the EEPROM access.

#### START AND RESTARTS

The node has the following types of restarts:

- 0      NODE WARM RESTART
- 1      NODE COLD RESTART
- 2      NPU COLD RESTART
- 3      APU COLD RESTART
- 4      APU WARM RESTART

During a restart the hardware within the scope of the restart will be tested.

All restarts shall be logged in the "error log". The reason for the restart shall be logged.

Each restart may be triggered by different conditions and behaves differently.

Restarts may be used for repair. A self-test that fails in a warm restart shall never result in a cold restart. This would lead to a situation where a control system failure could result in a traffic disturbance. There are one exceptions PCI access to the ASIC will lead to a cold repair.

A restart that affects the NPU (node warm/cold or NPU cold restart) shall not change the state of any LEDs on any other boards. An APU with a service LED on (in the board removal interval) shall not have the LED turned off by an NPU restart. The board removal interval is likely to become longer but the state of the LEDs shall not change.

A restart that affects the NPU (node warm/cold or NPU cold restart) shall give a PCI reset. Thus if the NPU for some reason is reset then all APUs connected to the PCI bus will be disconnected from it. The PCI reset shall be given both before and after the NPU executes the restart.

The node warm/cold and NPU cold restart restores the configuration file.

#### EQUIPEMENT INSTALLATION AND REPAIR

##### GENERAL

Main procedure:

It will be possible to request a board repair / removal by pressing the board removal switch (BR) on the front of the board. This disables traffic related alarms from the APU.

The yellow LED on the board will be lit when the board can be removed. The board is now placed in cold reset.

The LED will stay lit for a period of  $\tau_2$  seconds. (board removal interval/timer). During this time the board may be safely removed.

If an APU is removed it may be replaced during an interval of  $\tau_6$  min (board replacement interval/timer). If a new board of the same type is inserted into the same slot during this interval it will be configured as the previous board and will be taken into service automatically.

The procedure for removing a board shall thus be:

- Press the BR on the front.
- When the yellow LED is lit, the board can be removed within  $\tau_2$  sec and then if desired it could be replaced within  $\tau_6$  min.

APU variants:

- If the board is not removed during the board removal interval it will be taken into service at the expiration of

the board removal timer. This means that an APU warm restart is performed in order to take the unit into service again. Note that pressing the BR without removing the board is the same as cold starting the board.

- 5 • If the board is replaced by a board of a different type than the one before it will result in a loss of the previous board's configuration.

#### NPU variants:

- 10 • During the board removal interval the NPU does not have a HW warm reset signal asserted, but it is in a passive equivalent state.

- 15 • When the NPU enters the board removal interval it will execute a PCI reset. This is done so as to ensure that if the NPU is replaced the NPU cold restart will be done without a lot of PCI bus activity. It is also done to ensure that the link layer protection mechanisms are in operation during the NPU unavailability. If the APUs were placed in warm reset the MSP 1+1 of an LTU 155 board would become inactivated.

- 20 • Note that pressing the NPU BR without removing the NPU is the same as a NPU cold restart..

#### PFU variants

TN NE can be installed with or without power redundancy. Loss of power redundancy result in the notifications described in 0.

If administrative status is set to 'In Service' for all PFU (default), the system is configured with power redundancy. In order to make this possible the PFU modules has to be presented in the entity MIB even if only one PFU is installed.

#### FAU variants

TN NE can be installed with or without FAN unit.

If administrative status for FAU is set to 'In Service' (default), the system is configured with FAN unit.

35 In order to make this possible the FAU module has to be presented in the entity MIB even if no FAU is installed.

More details:

#### BNS-ANS interaction:

When the BR in the front of the board is pressed, the BNS will inform the application (ANS) that the board should be taken out of service.

When the application is ready, it will report to the platform that the board can now be removed. The BN will then deallocate the PCI device drivers for the board and light the board's yellow LED. The BNS shall then place the APU in cold reset so as to avoid signals from a board which is now unavailable to the ANS.

#### 10 Configuration:

Note that the **Running Configuration** of a board under repair will be lost if:

- The node powers down.
- The node/NPU restarts.
- 15 • The board is not replaced within the board repair interval.
- Another type of board is inserted in the slot.

When the board repair timer expires the board will be removed from running configuration and running configuration will be saved in the start-up configuration, i.e. the board can no longer be replaced without loss of the configuration.

If the save timer is running when the board removal timer expires then the configuration file save will not be executed.

#### BPI handling:

The applications are responsible for the BPI handling. The BPI interfaces can be enabled by the applications if required. The BPI bus shall be used by the ANS as follows:

- 30 • If an ANS has 2 boards connected to the 2BPI it may be enabled. If the application with an enabled 2BPI bus has less than two boards on the bus it shall be disabled at the expiration of the board removal timer.
- If an ANS has at least 3 boards connected to the 4BPI it may be enabled. If the application with an enabled 4BPI bus has less than two boards on the bus it shall be disabled at the expiration of the board removal timer.

- PtP BPI shall be disabled.

The BPI busses are disabled as a consequence of a node or APU cold reset.

### INSTALLATION

5 The following use cases require the operator to be present at site and to set the node in so-called node or NPU installation mode:

- 10 1 Installation of a new node (Node installation). The node doesn't have DCN links up and/or DCN configuration is wrong. I.e. the node is not accessible from a remote management site.
- 2 Change forgotten password (Node installation). Changing the passwords without the old passwords should not be possible remotely.
- 15 3 Fallback to old NPU software revision (Node installation). This is an emergency use case only applied in case a software upgrade prevents any other up/downgrades.
- 20 4 Repair of the NPU( NPU Installation). The new NPU, that replaced the defect one, has a different configuration than the previous one. I.e. the configuration file would cause traffic disturbance and the node is not accessible from a remote management site.

25 There are two ways to enter node installation mode:

- through pressing the BR button after node power-up (Use cases 1 to 3 above). During this period the red and yellow LED on the NPU are on.
- 30 • in case there is no configuration file present at restart.

Node installation mode has priority over NPU installation mode. That is to say that if a condition for node installation mode occurs, even when NPU installation mode was active, the former mode will be entered.

35 As there are four ways to enter NPU installation mode:

- Pressing the BR in the installation mode entry interval after NPU power-up (Use case 4). During this period the red and yellow LED on the NPU are on.

- There is no configuration start-up file present on the NPU (Use case 4).

- The software on the NPU doesn't match the System Release described in the configuration file and the node fails to upgrade.

- There is incompatibility between a SR (Software Release) and the Backplane type (Use case 4).

Both installation modes can always be left by pressing the BR. A automatic save of the running configuration to the start-up configuration is always performed.

LCT shall always be directly connected whilst a NPU or a node is in installation mode.

Special behaviour of the node in both installation modes:

- The node has a default first IP address.

- A DHCP server is running that provides the LCT with a second IP address.

- Default passwords are valid

- IP router function is disabled

- Operational status of the node shall be set to operational status "reduced service" and node equipment status "installation mode" and the yellow LED on the NPU shall be flashing (1 Hz).

- No 'save' time-out and manual 'save' not possible through the LCT.

- IP-address of the FTP as specified in the MIBs is ignored and the second IP address is always used.

- FTP user and password are default, i.e. 'anonymous'.

Each of the 4 uses cases that cause the node into installation mode are described in the next sections.

### Install node

For the installation of a new node the operator arrives with the equipment at the site and has a goal to get the node connected to the DCN after which configuration of the node can be performed remotely as well as locally. The use case is illustrated in Figure .

After the AMM is equipped with the necessary PIUs the operator will turn on the power. In order to enter installation mode he will press the BR as described in the previous section.

- 5 Since the configuration stored on the NPU may be unknown the operator is offered to delete the configuration, if one exists and return to factory settings. This means that the operator will have to perform a software upgrade in order to get the SRDF in the node.
- 10 In the case where a node is installed traffical disturbance is not an issue. A node power-up followed by an installation mode entry can therefore do a hardware scan to detect all APUs. The NE can then enable MSM/LCT access to the MCR application.
- 15 What is important first is to establish DCN connection of the TN NE. The TN NE is connected to the IPv4 based DCN through either PPP links running over PDH/SDH/MCR links or Ethernet. The SDH STM-1 links have a default capacity PPP link on both the RS and the MS layer, no configuration is  
20 needed for that. For DCN over E1 and MCR configuration is needed. In the DCN over E1 case a PPP link needs to be set-up over an E1.
- For MCR however frequencies have to be configured and antennas need to be aligned on both side of a hop. The  
25 latter requires installation personnel to climb in the mast, which due to logistics needs to be performed directly after hardware installation. For the MCR set-up the MSM must be launched. After MCR set-up is performed minimally required DCN, security and Software upgrade set-up can be  
30 either configured through the download of a configuration file or manually.
- The configuration file indicated in the automatic set-up is appended to the running configuration in order to keep the previous MCR set-up.
- 35 In both automatic set-up and manual set-up the operator is informed on the progress of the software upgrade. Complete new NPU PIUs from factory have a configuration file with correct SRDF info present. So here no software upgrade is needed.
- 40 After the set-up the inventory data and DCN parameters are shown to the operator, who will exit the installation mode through a command via the LCT or by pressing the BR.

The node will perform a save of the configuration and enter normal operation.

Figure 43 Install new node

## 5 Repair NPU

In case a NPU is defect, the operator can replace the NPU without disturbing traffic, except for traffic on the NPU. For this purpose he has to be on site with a configuration file of the defect NPU. This configuration file can be  
 10 obtained from a remote FTP server where the node has stored its configuration before. Or he can get it from the defect NPU in case this is still possible.

Since the node will be in installation mode while downloading the configuration file, i.e. has the first IP  
 15 address, the operator has to move the old configuration file from the directory named by the IP address of the old NPU to the directory named by the first IP address.

The NPU repair use case is illustrated in Figure . After the old NPU is removed and the new one is plugged in, the  
 20 operator has to press the BR to enter installation mode.

If he fails to do this the NPU will start-up normally and traffic can be disturbed due to an inconsistent start-up configuration file or in case no configuration file is present the NPU installation mode will be entered. Wrong  
 25 NPU Software will automatically lead to entering the NPU installation mode.

Since traffic is not to be disturbed the configuration file is not loaded nor is a hardware scan performed.

Since the username and password for the FTP server are set  
 30 to default the user is asked to enter the username and password he wants to use. This prevents the operator of having to define a new 'anonymous' user on the FTP server. After the operator has specified the name of the configuration file the node will fetch the file from the  
 35 FTP server on the locally connected LCT laptop. The SNMP object xfConfigStatus is used to check if the transfer was successful.

After that the installation mode is left and the node is warm restarted . Upon start-up the node will, if necessary  
 40 automatically update the software according to the downloaded configuration file.

## Figure 44 Repair NPU

### Change forgotten password

5 If the operator has forgotten the password for a specific node he will have to go to the site and perform a node cold restart, i.e. power-up, and enter installation mode. This will lead to traffic disturbance.

10 This operation is not possible in NPU installation mode since in NPU repair no hardware scan is performed and saving the running configuration (with the new passwords) would lead to an incomplete start-up configuration file.

The node will perform a hardware scan and load the start-up configuration file. Subsequently the operator can change the passwords and leave installation mode.

15 The use case is illustrated in Figure 45.

## Figure 45 Change forgotten password

### Emergency fallback NPU

20 This alternative is used when the user wants to force a NPU SW rollback to the previous SW installation. This alternative shall only be used if a SW upgrade has been done to a SW version, which in turn has a fault in the SW upgrade that prevents further upgrades.

The use case is illustrated in Figure 46.

25

## Figure 46 Emergency fallback NPU

### REPLACE A NODE

30 It will be possible to replace a complete node. The configuration file must then be uploaded from the old and placed in the new node.

Hardware of the new node must match the old one exactly. Only APUs placed in the same location will be able to get the previous configuration from the configuration file.

REMOVE A BOARD

Please note that if the procedure for removing of board is not followed, the node will do a warm restart.

The procedure for board removal is as follows:

5

Figure 47 Removal of board (for information only.)

10

If the board is not removed from the slot within a default period of time after the yellow LED has lit, the remove board request will time out and the board will be activated with the running configuration.

ADD BOARD TO EXISTING NODE

The BN will inform the application about the new APUs. The APU shall be given a default configuration.

15

For a new inserted board notifications are only enabled for board related notifications, not traffic related notifications.

REPAIR A BOARD

20

The node will hold the running configuration for a board for  $\tau_6$  minutes after this the board has been removed from the slot. This includes all alarms will stay active until either the board is completely removed or the new board clears the alarms.

The installation personal then has  $\tau_6$  minutes to replace the board with another of the same type.

25

When the new board is entered the running configuration will be restored to the board. It is also possible that a new ADS will be needed. SW upgrade can then be carried out from a file server or from the LCT.

REPAIR PFU

30

Non-redundant configuration

In order to handle the case where only one PFU is fitted, and it is to be replaced, a special procedures is implemented.

35

- Press the BR on the PFU.  
The NPU notifies the EM and lights the yellow LED.

- Remove the power and fan cable.
  - Replace the PFU.
  - Re-connect the power and fan cable.
- The node does a power-up.

#### 5 Redundant PFU configuration

If the node is equipped with redundant PFUs then a PFU repair can be done without taking the node down.

Note: Fan alarms are not suppressed.

#### REPAIR FAN

- 10 No repair procedure is needed for the fan. The NMS is notified when the fan is removed / inserted.

The replacement of the fan however needs to be quite fast, as the node will otherwise shut down due to excessive temperature.

#### 15 REPROGRAM PCI FPGA

- 20 The TN NE has been prepared for PCI FPGA reprogramming. The PCI bus has a programming bus associated with it. This bus is a serial bus that may be used by the NPU to reprogram the PCI FPGAs on all the PIUs in the node. This bus is included as an emergency backup if the PCI FPGAs must be corrected after shipment.

In order to utilise the programming bus the SW to handle it must be developed as this is not within the current scope of the system.

## INVENTORY HANDLING

When a new board is entered into the node, the board shall be activated and brought into service. A notification will be sent to the management system if a new board is detected.

Activation of a board implies:

- Activation of DCN channels
- Generation of entity MIB's
- Software upgrade if needed.

## MANAGEMENT

### Operational status

Operational status in TN is supported on the node, replaceable units and on interfaces (ifTable). This chapter describes the equipment (node and replaceable units) operational status. An equipment failure is the cause for an update of the operational status. The relation between equipment status severity and operational status is:

Operational status	Equipment alarm severity
In service	clear/warning
Reduced Service	minor/major
Out of service	critical

Operational status (Replaceable unit):

Replaceable units in TN are all boards (PIUs) and the fan.

**In service:** This status indicates that the unit is working properly.

**Reduced Service:** This status indicates that normally supported traffic functionality is available but that the management functionality is reduced. (Due to minor alarms like for example high temperature).

**Out of service:** This indicates that the unit is not in operation, i.e. a traffic disturbing failure has occurred. When a PIU is out of service it is in the cold reset state. For PFU and FAU this state is not traffic related but indicates either non-presence (administrative state=out of service or a critical defect in the equipment status).

#### Operational status (Node):

**In service:** This status indicates that the node is working properly.

**Reduced Service:** This status indicates that the traffic functionality in the backplane is available but that the management functionality (result of a minor equipment alarm) or a redundant function in the node is reduced/unavailable for which a further reduction will have impact on traffic.(result of a major equipment alarm).

**Out of service:** This indicates that the node is not able perform the traffic function properly.

### Equipment status

Equipment status in TN is supported on the node and replaceable units. This status gives more detailed information as background to the operational status. The status of a replaceable unit is independent of that of the node and vice-versa. A change in the equipment status leads to an update of the operational status and a possible alarm notification with the equipment status as specific problem.

### Replaceable unit

In addition to the operational status, the node supports equipment status on replaceable units. The equipment status may be one or more of the following:

Equipment Status	Severity	Operational status
In repair	Board removed=critical	Out of Service
High temperature	High=minor Excessive=critical	Reduced Service Out of Service
Hardware error	Control = minor TDM, Sync bus=major	Reduced Service Reduced Service

	Power, Traffic=critical	Out of Service
	For Fan fault=critical	Out of Service
Wrong software	minor / critical	Reduced Service / Out of Service
Unsupported unit type	critical	Out of Service
Wrong slot	critical	Out of Service

### Node

In addition to the operational status, the node supports equipment status on the node. The equipment status may be one or more the following values:

Equipment Status	Severity	Operational status
Power failure (redun)	major	Reduced Service

Traffical system failure	1 TDM/sync bus fails=major	Reduced Service
	2 or more TDM/sync busses fail=critical	Out of Service
Control system failure	Redundant NPU fails=minor	Reduced Service
	NPU fails=major  PCI failure on all boards or SPI self- test failure=major	
Installation mode	Node=minor  NPU=major (missed redundancy SNCP)	Reduced Service

#### Administrative status

It shall be possible to set the administrative status of the APUs as follows:

**In Service:**

**Out of service:** The APU shall be held in cold reset.  
Alarms/event notifications are disabled.

When an PIU's administrative state is set 'out of service'  
5 the operational status will show: 'out of service' with no  
active alarms in the equipment status. This implies that  
for active alarms a 'clear' trap will be sent.

A PFU or FAU that is set to 'out of service' is regarded as  
not present, i.e. no redundancy in case of PFU, and not  
10 taken into account for the node operational state. This to  
cover the case where a redundant PFU is wanted but it is  
detected faulty, i.e. not present. In that case the PFU is  
shown as administrative status 'in service' whilst  
operational status is out of service. At least one PFU in  
15 the node must have administrative status 'in service'.

**NODE CONFIGURATION HANDLING**

The node stores the configuration in one start-up  
configuration file. The file consists of ASCII command  
lines.

20 Each application has their chapter in the configuration  
file. The order of the application in the configuration  
file must represent the protocol layers. (SDH must come  
before E1 etc). Each application must specify its order  
in the start-up configuration file.

25 The start-up configuration is housed on the NPU, but the  
node is also able to up/down load start-up configuration  
from an FTP site.

- When the node is configured from the "SNMP / WEB / Telnet" it will enter an **un-saved state**. Only running configuration is updated, i.e. running is not equal to start-up configuration anymore. Entering this state will start a  $\tau_6$  minutes timer, successive configurations will restart the timer. The running configuration is saved when a save command is received before the timer expires. If the timer expires the node will do an warm restart and revert to the latest start-up configuration.
- 10 The node is also able to backup the start-up configuration file to an FTP server. This is done for each save command (not more frequently than  $\tau_6$  minutes).

#### Figure 47+1 Save command handling

- 15 Node generated save-command

The node updates the **start-up configuration** in the case of board removal (after  $\tau_6$  minutes timeout). The node is only updated in case of **saved state**.

#### Configuration validation

- 20 The configuration file shall include information about the AMM type for which the configuration is made.

Configuration files should not be exchanged between different backplane type. However in case e.g. an AMM 6p configuration file is used for a AMM 20p a kind of best effort will be done in configuring boards and node.

25

If the file contains configuration for an empty slot, that part of the configuration shall be discarded.

- If the file contains configuration for a slot not matching the actual APU type, that part of the configuration shall be discarded.
- 30

## FAULT HANDLING (EQUIPMENT ERROR)

### GENERAL

This chapter describes equipment errors in the node. The node handles single errors, double error is not handled.

- 5    Faults shall be located to replaceable units. Faults that cannot be located to one replaceable unit shall result in a fault indication of all suspect units.

- 10   The actions in this chapter are valid for units with administrative status set to 'In Service'. If a unit has administrative status set to 'Out of service' alarms shall be suppressed, and the unit is held in cold reset.

#### General fault handling

The figure below shows general principle of TN fault handling of hardware and software errors.

15

Figure 48 Fault handling of hardware and software error.

- 20   Fault handling includes handling of software and hardware faults. Other faults like temperature violation is not handled according to the state diagram above.

#### Node error handling

The figure 49 shows how the TN handles Node errors.

- 25   Figure 49   TN Handling of node error.

The Node fault mode is entered after 3 warm / cold fault restart within  $\tau_6$  minutes. In this mode is the NPU isolated from the APUs and fault information can be read on the LCT.

## APU error handling

The figure 50 shows how the TN handles APU errors.

Figure 50 TN Handling of APU/PIU errors.

5

### BOARD TEMPERATURE SUPERVISION

10 The ANS shall set the temperature tolerance of the board (default 70/75 °C for high/excessive). The BNS shall set the high and excessive temperature threshold as ordered by the ANS. The BNS shall accept and set values in the range 50 - 95 °C. Incorrect values shall result in default values and the operation shall be logged in the sys log.

BNS shall do the equivalent for the NPU and PFU boards.

#### Detection

15 Temperature will be measured on all boards in the node. Two levels of alarms shall be supported, excessive and high temperatures. The temperature sensor in the SPI BB will do this.

#### Notification

20 The PIU operational status shall be set to:  
minor/high temperature  
critical/high temperature

Depending on which threshold is crossed.

25 Note that this should not give any visual indications as the fault is likely to be either a fan failure or a rise in the ambient temperature.

#### Repair

30 The high temperature threshold crossing shall lead to a power save mode on the APU (set the board in warm reset). The PIU shall after this be taken in service again if the temperature on the board is below the high temperature threshold continuously for a period of  $\tau_2$  seconds.

Excessive temperature on the board shall result in a cold reset of the board. This second threshold level shall be handled by hardware and shall not be under software control. Board temperature reduction shall automatically take the boards into service again.

Excessive temperature on the PFU shall shut off power to the node. This function shall be latching, i.e. the power to the node shall be turned off before the power comes on again.

- 10 Based on high temperature the node will enter "node fault mode" (Isolated NPU, no access to other board). The mode will be released when the high temperature indication is removed.

#### FAN SUPERVISION

##### 15 Detection

The fan status is signalled on the SPI bus from the PFU. The signals only indicate OK/NOK. The individual fans are supervised and a failure is indicated if one fan fails.

A fan cable removal shall be detected as a fan failure.

##### 20 Identification

SPI signal.

Notification

The fan operational status shall be set to: critical/hw error.

##### 25 Notification / alarm to NMS

The fault LED on the fan shall be lit.

Repair

Manual replacement.

- 30 The fault may in addition result in temperature supervision handling.

BOARD TYPE NOT SUPPORTED

## Detection

The SPI indicates the NPU SW does not support a board type.

## Identification

- 5 The SPI inventory information displays a board not supported by the NP SW.

## Notification

The APU operational status shall be set to:critical/unsupported type.

- 10 The APU fault LED shall be lit.

Notification will be sent to the NMS.

## Repair

None, The board will be held in cold reset.

15 APU-POWER

## Detection

- 20 The basic node shall supervise that the APUs has a correct local power. This is supervised through the use of local power sensors. A power sensor fault will normally indicate that the APU has had a power dip.

## Identification

SPI signal.

## Notification

- 25 The power LED shall be turned off and if possible the fault LED shall be turned of during the time that the power is faulty.

The APU operational status shall be set to:  
critical/hw error

- 30 The error will be reported to the application, and then to the EEM

## Repair

The board will be held in cold reset to power is back.

## PFU/ INPUT POWER SUPERVISION

### 5 Detection

The PFU will detect loss of incoming power or PFU defect with loss of incoming power as a consequence. This can of course only be detected when redundant power is used.

### Identification

### 10 The PFU geographical address.

### Notification

The NE operational status shall be set to:  
major/power failure

### 15 The PFU operational status shall be set to: critical/hardware error

Alarm will be sent to the EEM.

Fault LED on PFU on and power LED on PFU off while the power is faulty.

### Repair

### 20 None

LED INDICATIONS

The following LED indications shall be given on the PIUs:

Unit	Green LED	Red LED	Yellow LED	Description/state
All	●	-	-	Power OK
All	-	●	-	Faulty unit, wrong slot, unsupported board.
All except FAU	-	-	●	Board may be removed (board removal interval) The FAU doesn't have yellow LED
PFU	○	●	-	Power delivery failure red. pwr. - unconnected power cable - PFU failure (fuse, SCP..)

## Traffic Node: Software Upgrade

### Scope

5 The document describes the software upgrade functionality offered by the TN. It specifies the functionality for upgrading one TN, not the functionality offered by external management to upgrade a whole network, like how to upgrade from network extremities back to the BSC or how to  
10 upgrade several TNs in parallel.

*Italic functionality is not part of R1 but will have postponed trouble reports written for them.*

### General

15 Software Upgrade is the common name for Remote Software Upgrade (RSU) and Local Software Upgrade (LSU). Where RSU is defined as software upgraded from a remote FTP server whilst for LSU the local PC is used as FTP server.

20 Software present on a TN is always according to a defined System Release (SR). A SR is a package of all software that can be replaced by a SU of the software for:

- TN Basic Node Software (BNS) in the NPS load module
- Application Node Software (ANS) in the NPS load module
- Application DP Software (ADS), i.e. APU with DPs

The TN uses FTP for both RSU and LSU.

25 A TN is always upgraded to a SR. A SR contains always all BNS, ANS and ADS for that specific release. When performing a RSU or LSU, it is always from one SR to another.

### Futures

Upgrade of AAS is for the future.

### 30 FTP server

Software is transferred to the TN using the FTP both for RSU as well as LSU. BNS has an FTP client that can download files from an FTP server.

The server is either on the DCN or in a locally attached PC, there is no difference between RSU and LSU except for speed.

For RSU there must be an FTP-server somewhere on the DCN. Considerations must be taken to the DCN topology to avoid the RSU taking too long. Even if the network is okay from a traffic point of view, this might not be the case in the DCN point of view. There can be a need of several ftp-servers on the same DCN. The files to be downloaded to the TN then have to be pre-loaded to the local ftp-servers.

For LSU an FTP server has to be installed on the LCT PC.

### System Release structure

An TN System Release (SR) consists of load modules for each type of processor software in the TN, and a System Release File (SRDF) describing the contents of the SR.

The SR must be backward compatible at least two major customer releases. This to limit testing of software upgrade/downgrade, e.g when R6 is released it will have tested against R4 and R5.

It shall be possible to have different SRs running on different TNs within one TN network.

### The System Release Description File

As the SRDF file name and ftp-server location are given as MO's, see XF-SOFTWARE-MIB. Nodes can be given different SRDF files and thereby run different Software, i.e. contain different load modules.

SRDF is a CLI script file that is transcribed into the XF-SOFTWARE-MIB when downloaded and thus read-only. It is the only way to get information about load modules to the TN. The syntax and semantics of the SRDF shall be revision controlled. It shall be possible to add comments to the SRDF. This can for example be used to indicate the APUs a certain DP software module belongs to.

Each TN System Release will be represented by a directory on the ftp-server named by the product number and version of that release and contained by an `tn_system_release` directory. All load module plus a `srdf.tn` file reside within one System Release directory. Product number and revision will denote each individual load module. For example:  
`tn_system_release/`

<name_of_release>	directory	
srdf.tn		SRDF-file
CXP901584_1_R1A		NPU load module file
CXCR102004_1_R1B		LTU 155 load module
5 file		
<number_MMU>_R2A		load module file
<number_MMU_RAU>_R1A		load module file

10           Figure 51 example of TN System Release structure  
 An optional header can include e.g. revision, hardware-version, and checksums, to enable BNS to control that it is the correct load module that has been loaded. Some of this information shall be included in the SRDF file as well.

15   The TN Basic Node shall provide a RAM-disk of 6 MBytes for software upgrade of DP's.

#### The XF-SOFTWARE-MIB

All control and information regarding software upgrade will be represented by Managed Objects in the XF-SOFTWARE-MIB.

20   For each TN two System Releases will be defined in the XF-SOFTWARE-MIB, one Active System Release and one Passive System Release. For each System Release the overall product number and revision is presented in the XF-SOFTWARE-MIB as well as the product number and revision of  
 25   each load module contained by the corresponding System Release.

30   The active SR shows the current SR running on the TN and is a reference for new boards as to what software should run on the board in order to be compatible with the rest of the node.

The passive SR describes the previous SR the node was upgraded to whilst in normal operation. During the software upgrade process the passive SR will describe the software the TN is currently upgraded to.

35   The XF-SOFTWARE-MIB Software shows the product number and revision of current running software in the active memory bank for each APU and those for the software in both active and passive of the NPU

### The Software Memory Banks

Each APU/NPU with a DP contains two flash memory banks, an active and a passive one. The flashes are used to contain the current and previous software for the corresponding APU/NPU. The software in the active bank is the one running. The one in the passive bank is used to perform a fallback to a previous System Release for that APU/NPU whilst a new software upgrade is being tested.

The software in the passive bank can also be used to perform a manual switch to previous software for the NPU. This is not a normal situation procedure and can only be performed in installation mode. It should only be used in emergencies and is against the policy that a node only runs a tested SR.

The software modules described in the active SR will always be present in the active memory bank of the respective NPU or APUs.

The passive memory bank can contain the following software:

1) The load module as described in passive SR. In this case the load module in the passive SR is different than the one in the active SR. In case of a fallback the APU/NPU will switch to the passive memory bank if it is a part of the passive SR.

2) The load module does not correspond with either active nor passive release in case:

a) The load module had the same release in the last two upgrades. In this case a fallback will not lead to a memory bank switch.

b) The APU was inserted into the system after a software upgrade of the TN as a whole. In this case, automatic software upgrade of this single APU is performed as described in 0. In this case fallback is not an option as can be read in 0.

The various cases are illustrated in Figure 52 below.

Figure 52 Illustration of the various contents of the APU/NPU memory banks

## Upgrade of a node to a System Release

### Normal procedure

The main software upgrade sequence is the one performed remote or local, i.e. from an EM or EEM, for a whole node.  
 5 Special cases are described in the following sections.

Before starting a software upgrade the FTP server location (IP address) and username/password must be specified.

The software upgrade sequence is started with the EM/LCT changing objects in the TN describing the product number and revision of the SR to upgrade to. Once the EM/EEM  
 10 starts the upgrade process the TN will ask for the SRDF-file via its FTP client on location:

The `tn_system_release` is the directory under which all SRs for TN are available. This is not configurable by the  
 15 EM/LCT:

When the SRDF-file has been downloaded, evaluated and represented in the XF-SOFTWARE-MIB, the TN will download the necessary load modules via its FTP client to its RAM-Disk.  
 20

For the software upgrade process to proceed fast enough, the FTP server is assumed to have a limited number of client connections open at a given time. So in case of an upgrade of a whole network, few high-speed connections are  
 25 preferred over many low-speed connections.

The whole process is illustrated in Figure 53 below.

A load module downloaded to the RAM-disk on the NPU must be marked read-only until the respective controlling program, i.e. ANS, has finished the download to the target FLASH.

30 The new software is now marked to be used after a warm-restart of the TN and the EM/LCT orders a warm-restart directly or scheduled at a given date and time.

The warm-restart at a specified date and time will be used if many nodes are upgraded and have to be restarted at  
 35 approximate the same time to have the OSPF routing tables update as soon as possible.

Marking the new version for switching will happen at the given date and time just before the warm-restart.

During the warm-restart of the TN all ANS will check their APU's (by self-tests) to see whether the correct ADS is running. APUs that are in cold reset are not tested in the test run. If all was OK, the EM/EEM-user will be notified about this. The EM/EEM-user shall then have to commit, within a certain time, the new System Release. If no commit is received by the TN in time a fallback will be performed, i.e. it will mark the old revision as active and perform a warm-restart again.

The operator can also indicate a so-called node initiated commit. In that case the operator doesn't have to commit the new software, but the node checks whether it still has DCN connectivity. In case DCN connectivity was lost as a result of the software upgrade a fall-back will be performed.

*A node initiated commit will be default when executing a scheduled SU.*

The progress of the LSU/RSU process shall be available through status MO's in the XF-SOFTWARE-MIB.

Figure 53 The Software Upgrade process illustrated

#### Failure of upgrade of APUs as part of a system realease

In order to have a consistent and tested SR running on the TN APUs that fail to upgrade as part of a SR upgrade will be placed in warm reset in test phase and after a commit. This means that traffic will be undisturbed but that the APU is not longer under control of the NP software.

Another attempt to upgrade the board will be made when the APU or TN is warm/cold restarted.

#### Hot swap during upgrade

A board inserted during the software upgrade process will be checked/upgraded according to the active SR. It will not be upgraded as part of the upgrade to the new System release but as part of the test phase of the new system release.

#### No load module for APU

If no load module is present in the new SR for an APU type, these APUs will be set in warm reset and upgrade to the new SR will continue?

### Equipment error during software upgrade

Any form for equipment error during software upgrade will lead to abortion of the software upgrade process, which will be notified to the EM/LCT-user.

- 5 If an APU is in the cold/warm reset state due to e.g. "hardware error", "administrative state down" or "excessive temperature" it shall still be possible to perform a software upgrade of a SR. The specific board will not be upgraded. But the software upgrade will fail if the  
10 equipment status on an APU changes during the upgrade.

### SR download failures

The following failures can occur during download of SRDF and load modules for a SR:

- FTP server/DCN down; the access to the FTP client  
15 times out
- Wrong username/password
- Requested directory/file not found on FTP server
- Corrupted load module

20 All these cases 3 attempts will be undertaken. Failure after 3 attempts leads to abortion of the software upgrade (in case of SRDF) or placing the corresponding APUs in warm reset as stated in 0.

### Fallback

25 After a switch to the new SR, i.e. an TN warm-restart, the TN goes into a test phase. The test phase will end when the COMMIT order is received from external management. After the COMMIT order is received, there will be no fallback possible. Situations that will initiate a fallback are:

- COMMIT order not received, within  $\tau_6$  minutes after the  
30 switch
- Warm/cold node restart during the test phase.

If one of the situations mentioned above occurs, then the NPU will switch SR (fallback). Then the APUs will be ordered to switch software according to the previous SR.

35 Manual/ forced fallback is not supported in the TN.

### SU not finished before scheduled time

*In case the downloading of all required load modules is not finished 17 minutes before the scheduled time, the whole SU will be aborted and the operator will be notified.*

5

### Software upgrade of single APUs

#### Normal procedure

In order to have a consistent SR running on the TN APUs that are restarted have to have the correct software in respect to the SR. A restart of a APU can be caused by:

- The operator who initiates a cold restart of the APU
- An APU being inserted
- A cold/warm restart of the node. Only APUs in warm reset will then be restarted.

The principal of 'plug and play' shall apply in these cases, which means that the restarted APU shall be automatically upgraded:

- Check out whether the software revision according to the active SR is already on the APU (passive or active mememry bank).
- If not, download the corresponding load module and then switch software on that board.
- The board will then run software according to the active SR, but the software in the passive memory bank might not be according to the passive SR.

BNS does not update both banks. Manual/ forced fallback is not supported in TN.

When no boards are inserted since last software upgrade a fallback of the whole node could be achieved by downgrading the software. In that case only the SRDF has to be downloaded, since the previous software is still in the passive memory banks.

The ANS shall be able to communicate with older ADS when it comes to SU.

Figure 54 Su of a single APU due to a APU restart

## Figure 55 Hot Swap Software Upgrade

### New board type inserted

5 In case a new board type is inserted for which there is no  
ANS on the NPU. The APU will be marked not-supported and  
placed in cold reset.

### Failure of upgrade of APUs

10 In case SU for a single cold restarted APU fails, three  
attempts will be made before the APU will be placed in cold  
reset.

In case SU for a single warm restarted APU fails, three  
attempts will be made before the APU will be placed in warm  
reset.

### Load module download failures

15 The following failures can occur during download of a load  
module for a DP:

- FTP server/DCN down; the access to the FTP client times out
- Wrong username/password
- 20 • Requested directory/file not found on FTP server
- Corrupted load module

For all these cases section 0 applies.

### New system release already in passive memory bank

25 In case the new DP is already in the passive memory bank of  
the. Then there is no need for downloading the load modules  
for that APU.

### Load module not specified

30 If a load module is not specified in the SRDF, there can be  
no upgrade of that APU. The APU will be placed in cold  
reset.

### Fault during flash memory programming

If an error occurs in the process of programming the flash the TN will be notified and the whole upgrade process is aborted. The equipment status (hardware status) of the  
 5 faulty board will be set to hardware error (critical), i.e. Out of Service, this will light the red led on the APU. The ANS must handle Flash located on the APU.

### Special NPU cases

#### Upgrade of non-TN boards

10 If the NPU software does not handle the upgrade, e.g. in the MCR Link1 case, the NPU software will only be aware of the hardware through the equipment handling of the board.

#### No SRDF available

15 When no SR information in the configuration file is present on the NPU the node will enter NPU installation mode upon restart..

#### Incompatible software and AMM

20 In case the active software is incompatible with the AMM or doesn't recognize the AMM, the node will go in NPU installation mode upon restart..

#### Requirements to the configuration file

The SU configuration command saved in the configuration file must be backward compatible.

#### Upgrade time

25 In this chapter an estimate is made for both LSU and RSU.

#### RSU

30 In order to estimate the total RSU time for a reference TN network topology as described in Feil! Fant ikke referansekinden. and a structure as shown in Figure 56 the following characteristics are assumed:

- 16 Mbytes in a SR
- 512 kBits/s DCN in the SDH ring
- 128 kBits/s DCN on the radio links
- no IP congestion and overhead
- 35 • 5 TNs in the STM-1 ring
- four MCR sub-branches per TN in the STM-1 ring
- a depth of MCR sub-branch of 3

Figure 56 TN reference network topology

5 A typical RSU time can be calculated. It will take  $16 \times 8$  [Mbit] / 0,512 [Mbit/s] = 250 seconds in the STM-1 ring per TN and  $16 \times 8$  [Mbit] / 0,128 [Mbit/s] = 1000 seconds in the MCR branch.

10 A MCR branch can have four (512/128) sub-branches without adding to the download time, i.e. software to a TN in each of the branches can be performed in parallel.

In the MCR branch, however, downloads must be serialised at 128 Kbits/second.

15 For a reference network with 5 TN in the STM-1 ring and four MCR sub-branches with a depth of three, i.e a TN sub-network of 60 NEs, the download time is:

$$5[\text{SDH NE}] * 250 [\text{sec/SDH NE}] + 5 [\text{SDH NE}] * 3[\text{TN/Branch}] * 1000[\text{sec}] = 16250 \text{ sec} = 4.5 \text{ hours}$$

20 Each SDH NE plus its 4 branch, depth 3 sub-network RSU will require 3250 seconds, about one hour, longer.

Every 4 extra branches for a SDH NE will require 1000 seconds per TN in a branch. Say roughly one hour, assuming a depth of 3 to 4, per 14 TNs.

25 The actual erasing/programming of the flash memories adds to these times. Estimated programming times of flash are 14seconds/Mbytes to erase and 6 seconds/Mbytes to program. Which adds to 320 seconds for 16Mbyte.

30 However we cannot just add the download time and flash programming time, because a smart system will probably use the erase time on a node to download etc.

In requirement 47A a maximum time of 8 hours is required, which is fulfilled for the assumed reference network when programming and downloading are two parallel processes. However an extra hour is required for each new branch, of  
35 depth 3 to 4. Which means that requirements will be fulfilled for TN sub-networks with up to

$$8\text{hrs} = 28800 \text{ sec} / (3250 \text{ sec} / (1+3 \times 4) \text{ NES}) = 115 \text{ TNs.}$$

The maximum time for RSU of an TN from EM is  $\tau_8$  minutes.  
(Requirement 48A according to.....)

### LSU

For LSU the sum is much simpler: LCT on the site-LAN with a speed of 10Mbit/s, but 3Mbit/s available to the LCT, will approx. require  $16 \text{ [MByte]} * 8 \text{ [bit/Byte]} / 3 \text{ [Mbit/s]} = 42$  seconds. Note that no message overhead is assumed.

For LSU the erase time per Mbyte flash memory is longer than the download time but this can be done in parallel for all passive memory banks in all APUs, whilst down loading modules. The biggest single memory bank will be on the NPU (8 Mbytes) which will take 112 seconds to erase. Programming will then take  $16 * 6 \text{ seconds} = 96$  seconds. Erase plus program time is then around 208 second as a resulting LSU time.

The maximum time for LSU from LCT is  $\tau_7$  minutes.  
(Requirement 46B )

Note that while in the foregoing, there has been provided a detailed description of particular embodiments of the present invention, it is to be understood that equivalents are to be included within the scope of the invention as claimed.

## TERMINOLOGY

(Sorted by subject)

### Application:

5 Board specific SW and hardware (SDH-TM is an application)

### High Availability:

10 Notation from cPCI standards characterising the ambition level of the system with respect to availability. In this document it mainly refers to the module in the basic node which is responsible for SW supervision and PCI config.

### Platform:

Basic Node.

### Fault detection:

15 The process of detecting that a part of the system has failed.

### Fault identification:

The process of identifying which replaceable unit that has failed.

### Fault notification:

20 The process of notifying the operator of the fault.

### Fault repair:

The process of taking corrective action as a response to a fault.

### Warm reset:

25 This is a signal on all boards. When pulsed it takes the board through a warm reset (reset of the control and management logic). While asserted the unit is in warm reset state. The PCI FPGA will be reloaded during warm reset.

### Cold reset:

30 This is a signal on all boards. When pulsed it takes the board through a cold reset (reset of all logic on the board). While asserted the unit is in cold reset state. The cold reset can be monitored.

Warm restarts

A restart of the control and management system. Traffic is not disturbed by this restart. The type of restart defines the scope of the restart, but it is always limited to the control and management parts. During the restart the hardware within the scope of the restart will be tested.

Cold restart:

A restart of the control and management - and the traffical - system. This type of restart will disable all traffic within the scope of the restart. The type of restart defines the scope of the restart. During the restart the hardware within the scope of the restart will be tested.

Temperature definitions:High temperature threshold:

The threshold indicates when the thermal shutdown should start. The crossing of the threshold will give an SPI interrupt to the NPU.

Excessive temperature threshold:

The threshold indicates when critical temperature of the board has been reached. The crossing of the threshold will give a cold reset by HW and an SPI status indication to the NPU.

Excessive temperature supervision hysteresis:

The high and excessive temp thresholds determine this hysteresis. If the excessive temp threshold is crossed then the cold reset will not be turned off until the temp is below the high temperature threshold.

High temperature supervision "hysteresis":

The high temperature supervision will make sure that the board has been in the normal temperature area continuously for at least  $\tau_2$  seconds. before the warm reset is turned off.

Normal temperature:

In this area the boards are in normal operation.

High temperature:

In this area the boards are held in warm reset. This is done in order to protect the system from damage. The shutdown also serves as a means for graceful degradation as the NP will deallocate the PCI resources and place the APU in warm reset thus avoiding any problem associated with an abrupt shutdown of the PCI bus.

Excessive temperature:

In this area the boards are held in cold reset. The SPI block (HW only) does this when the excessive temperature threshold is crossed. This is done in order to protect the system from damage.

Running configuration:

This is the active configuration of the TN node. See chapter 0 for more details.

Start-up configuration:

This is a configuration of the TN node saved into non-volatile memory, the running configuration is stored into the start-up configuration with the save command. Node and NPU restarts will revert from running to start-up configuration.

Administrative Status:

This is used by the management system to set the desired states of the PIUs. It is a set of commands that sets the equipment in defined states.

Operational Status:

This information describes the status of the equipment. Management can read this. Operational status is split into status and the cause of the status.

Board Removal Button (BR):

This is a switch located on the front of all boards. If it is pressed this is a request to take the board out of service (see service LED). On The NPU this switch is used to place the node and the NPU in installation mode.

Service LED:

This is a yellow LED indicating that the board can be taken out of the subrack without disturbing the node. The service LED on the NPU will also be lit during the period after a node or NPU power-up in which the board may be placed in installation mode. When the node is in installation mode the yellow LED on the NPU will flash. The term yellow LED and service LED is in this document equivalent.

Power LED:

This is a green LED indicating that the board is correctly powered. The term green LED and power LED is in this document equivalent.

Fault LED:

This is a red LED indicating that a replaceable unit needs repair handling. The NPU fault LED will be on during NPU restarts until the NPU self-test has completed without faults. The APU will have fault LED default off. The NPU fault LED will flash to indicate node/bus faults. The term red LED and fault LED are in this document equivalent.

Node Installation mode:

This is a state where the TN may be given some basic parameters. The mode is used to enable access during installation or after failures.

NPU Installation mode:

This is a mode for repair of the NPU. The mode is used when a new NPU is installed in an existing node.

Node Fault mode:

The Node fault mode is entered after 3 warm / cold fault restart within  $\tau_6$  minutes. In this mode is the NPU isolated from the APUs and fault information can be read on the LCT.

Board repair interval (BRP interval)

This is the interval during which an APU and PFU may be replaced with an automatic inheritance of the configuration of the previous APU.

Board repair timer (BRP timer)

This timer defines the board repair interval. It has the value  $\tau_6$  minutes.

Board removal interval (BRM interval)

This is the interval during which an APU may safely be removed from the subrack. A yellow LED on the PIU front indicates the interval.

Board removal timer (BRM timer)

This timer defines the board removal interval. It has the value  $\tau_2$  seconds.

Save interval

- 5 This is the interval after a configuration command to the NE in which the operator must perform a save command.

Save timer

This timer defines the save interval. It has the value  $\tau_6$  minutes.

- 10 Installation mode entry interval (IME interval)

This is the interval after a node or NPU power-up in which the node may be placed in installation mode.

Installation mode entry timer (IME timer)

- 15 This timer defines the Installation mode entry interval.  
The specific value of this timer will not be exact but it shall be minimum  $\tau_3$  seconds (depends on boot time).

**BEST AVAILABLE IMAGES**

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☐ **BLACK BORDERS**
- ☐ **IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- ☐ **FADED TEXT OR DRAWING**
- ☐ **BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- ☐ **SKEWED/SLANTED IMAGES**
- ☐ **COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- ☐ **GRAY SCALE DOCUMENTS**
- ☐ **LINES OR MARKS ON ORIGINAL DOCUMENT**
- ☐ **REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- ☐ **OTHER: \_\_\_\_\_**

**IMAGES ARE BEST AVAILABLE COPY.**

**As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.**
